

Kevin's Mobile Grooming

From scattered text messages to one organized booking inbox.

The problem

Kevin loses appointment requests in text conversations. He needs a simple way for clients to request a visit, review every request in one place and notice new arrivals.

The customer experience

Customers create an account, confirm their email and request grooming with their dog details, an optional private photo, service, preferred date, contact information and address. Their account shows only their own requests and visit history. A preferred date is a request; Kevin still agrees the price and appointment time with the customer.

The business workflow

Kevin signs in through a separate administrative page. One inbox supports search, status filters and new-request badges. He can contact customers, confirm visits, mark them completed or decline them. Explicitly confirmed deletion removes a request and its contact details from the active database. Declining a request only changes its status.

A schedule that protects Kevin's time

Confirmation reserves the visit duration plus travel time after it. Overlapping confirmed visits are rejected by the database, including simultaneous attempts. For example, a 10:00 visit lasting 60 minutes with 20 minutes of travel reserves Kevin until 11:20. This MVP assumes one groomer; duration and travel are entered manually.

Data, access and notifications

Sites/Cloudflare hosts the app. Supabase provides the PostgreSQL database and account authentication. Customers see their own records; authorized administrators manage the business inbox. A separate practice workspace contains fictional data. The open inbox checks for new requests every eight seconds and offers optional browser notifications. Brevo emails customers when Kevin confirms a real visit or cancels a confirmed visit. Failed sends remain visible for review or retry. The demo sends no email. SMS and closed-browser push are not included.

Why this solves the issue

Every request has a persistent record and a clear next step. Kevin can distinguish new, confirmed, completed and declined visits without searching old message threads. Customers can follow the result through their own account.
