

Kevin's Mobile Grooming

A single place for every appointment request

Kevin loses appointment requests in text conversations. This MVP gives clients a simple booking-request page and gives Kevin a persistent, organized inbox, so he can see who needs a reply and keep each visit moving.

01

Request a visit

Clients enter their dog, service, preferred date and time window, contact details, address, and care notes.

02

Review and respond

Kevin sees new requests, unread counts, searchable client details, and the status of every visit.

03

Confirm and complete

After agreeing the time and price with the client, Kevin confirms the visit, then marks it completed.

How this solves the chaos

One reliable inbox. Requests survive reloads and device changes. New, confirmed, completed, and declined statuses replace the need to reconstruct a booking from messages.

Visible new-request alerts. The open workspace checks for new requests every eight seconds, shows an in-page notification and unread badge, and can send browser notifications when permitted.

A small complete workflow

The mobile-friendly form validates required details and rejects past dates. A receipt makes clear that the request is still awaiting confirmation. Kevin can call or email from the request, record an agreed time, decline or reopen it, and complete the visit. Duplicate retries do not create duplicate requests.

Built to be demonstrated safely

React and TypeScript run on a Cloudflare Worker with D1 storage. Real client records are restricted to the configured owner through server-side sign-in checks. An isolated practice workspace contains fictional appointments so reviewers can try the complete flow without accessing real clients.

MVP boundary. Alerts require an open workspace; this version does not send automatic SMS, email, or closed-browser push. Kevin still agrees price, route, and availability personally. The app records confirmation but does not contact clients for him.
